

Sand Dune Stabilization Methods – A Global Tour

Desert Research Institute

**Great Basin Unified
Air Pollution Control District**

**Keeler Dunes Meeting
August 24, 2011**

Global Sand Dune Stabilization

- USA**
- China**
- Sahara**
- Western Africa**
- Australia**
- New Zealand**
- Great Britain**
- Kuwait**
- Pakistan**
- India**
- Madagascar**
- Brazil**

Stabilization Methods

- Sand fences
- Straw (checkerboard and bales)
- Mats and netting
- Chemical spray
- Brush
- Vegetation – preferred method worldwide

Vegetation

- **PROS** - most effective, least expensive, aesthetically pleasing, mimics a natural system, self-repairing
- **CONS** – irrigation needed, plant establishment phase critical, maintenance required until self-sustaining system is developed

A photograph of a vast, sandy desert landscape. In the distance, there is a small cluster of buildings, possibly a oasis or a small town. A person is walking towards the right side of the frame, pulling a simple wooden cart. Two horses are harnessed to the cart, moving across the sand. The terrain is marked by numerous tracks and ripples from previous passage.

China

**Aerial Image of Shapatou area in 1956 with railroad line (A-B) engulfed in sand.
(From Mitchell et. al.)**

Straw Checker Boards

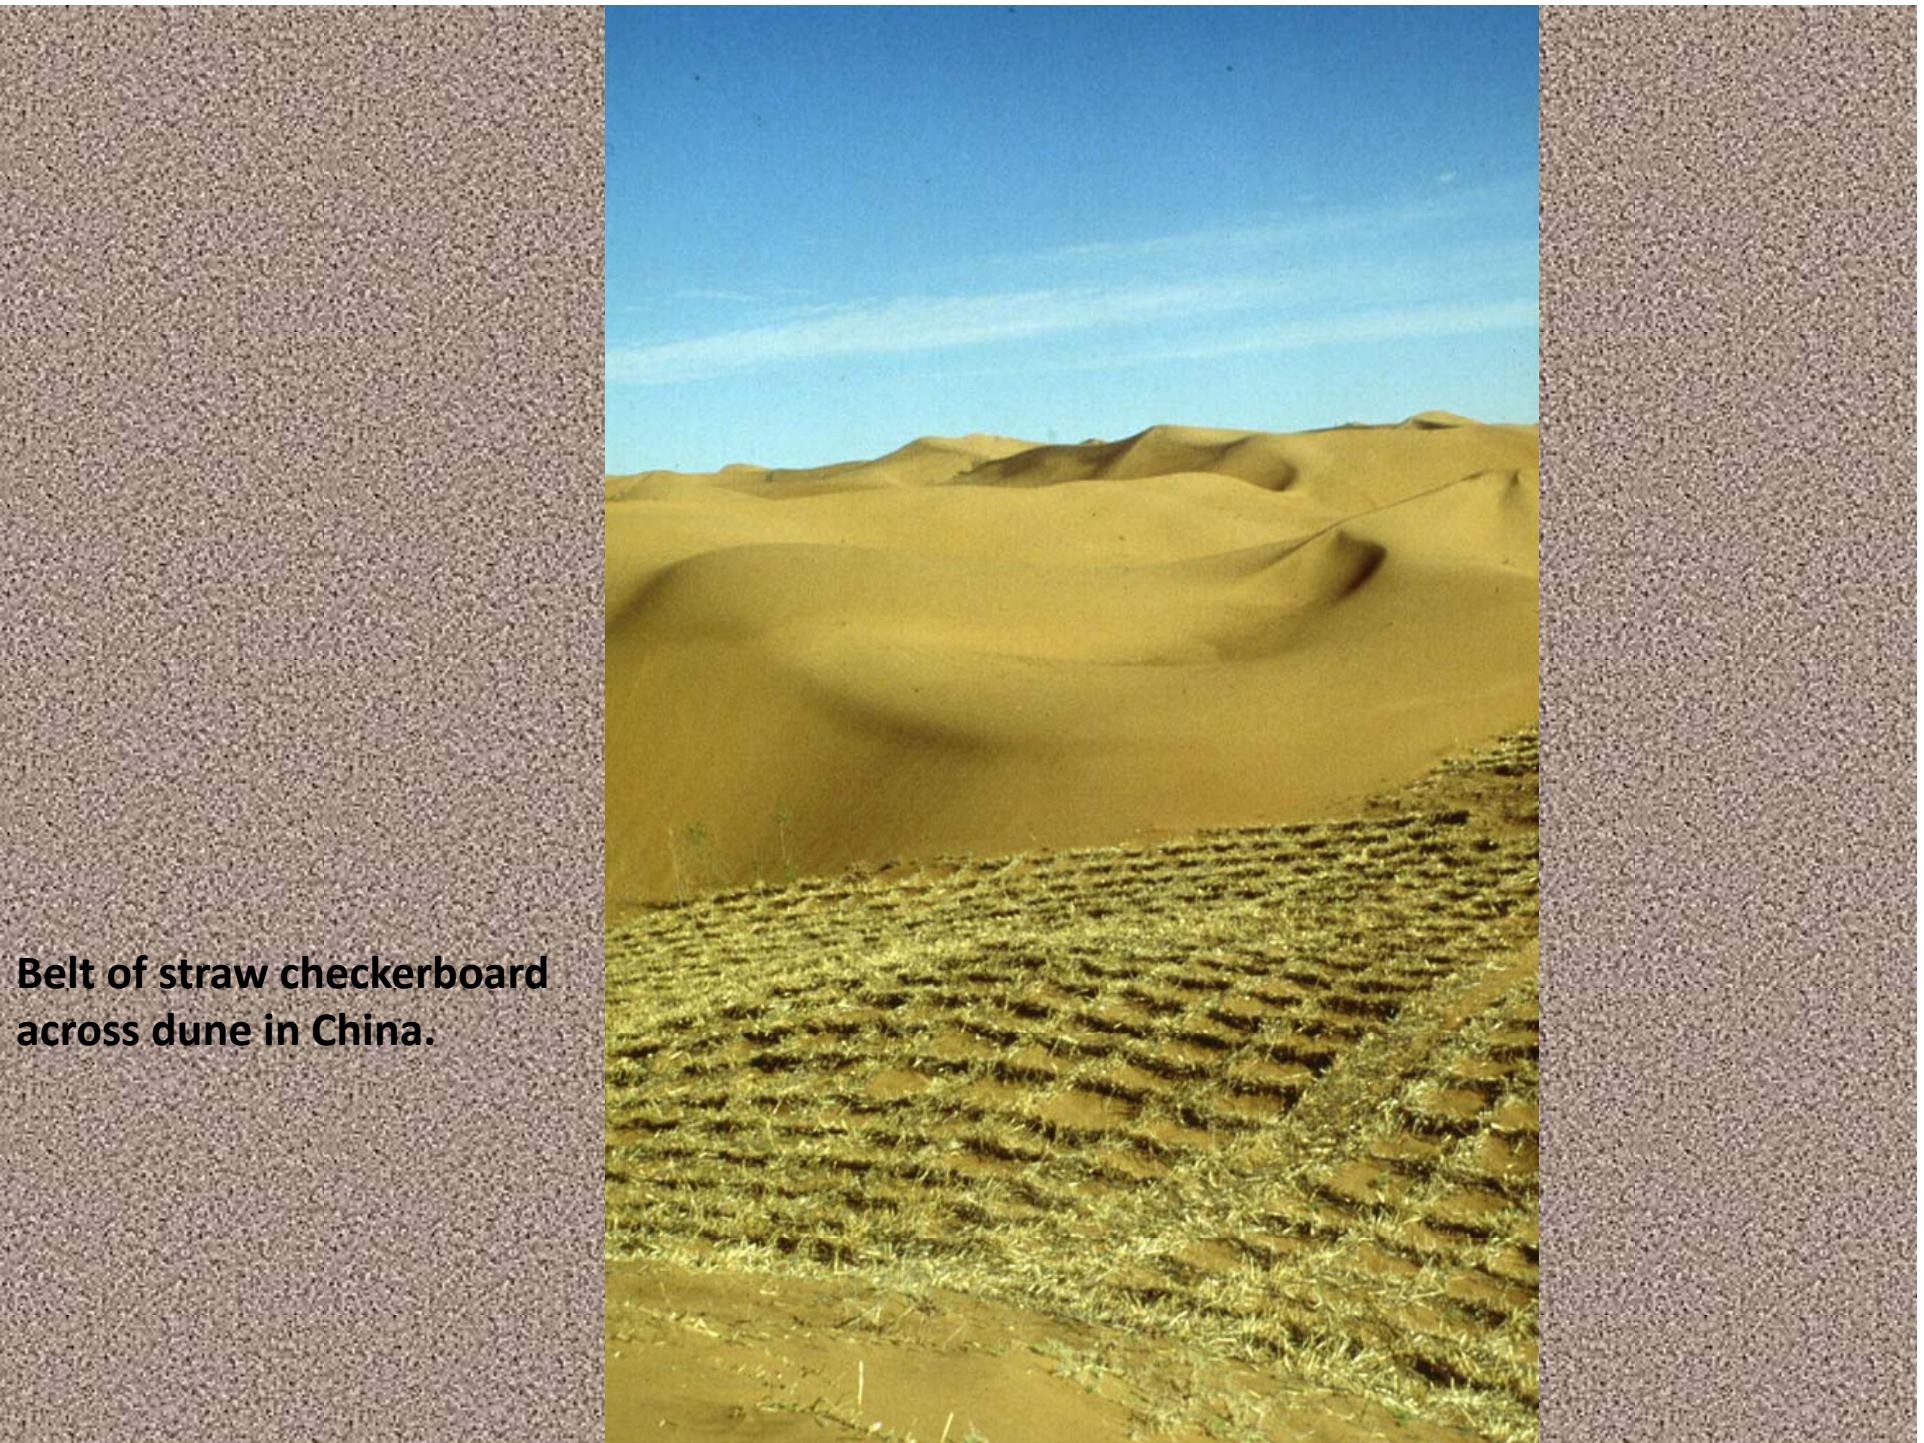

- Extensively used in China since 1950's
- Wheat or rice straw or reeds (50 – 60 cm in length) are placed vertically to form the sides of the checkerboard, which are typically 10 – 20 cm high.
- optimum grid size ranges from 1 x 1 m to 2 x 2 m, depending on local wind and sand transport conditions
 - Smaller grids in areas of stronger winds

**Straw Checkerboards
Shapotou, China**

Dune stabilized in 1981 with lines of trees and shrubs and straw checkerboard.

(From S. Jamieson, 2010)**

Sand Fences

- Widely used in coastal areas
- Most effective configuration
 - single linear fence perpendicular to the predominant sand transport direction
 - Fences 1.2 m (4') high, with a vertical arrangement of 3.8 cm (1.5 inch)-wide wooden slats with a gap of 2.5 cm (1 inch), giving a porosity of 50% are the most effective.

Sahara Desert

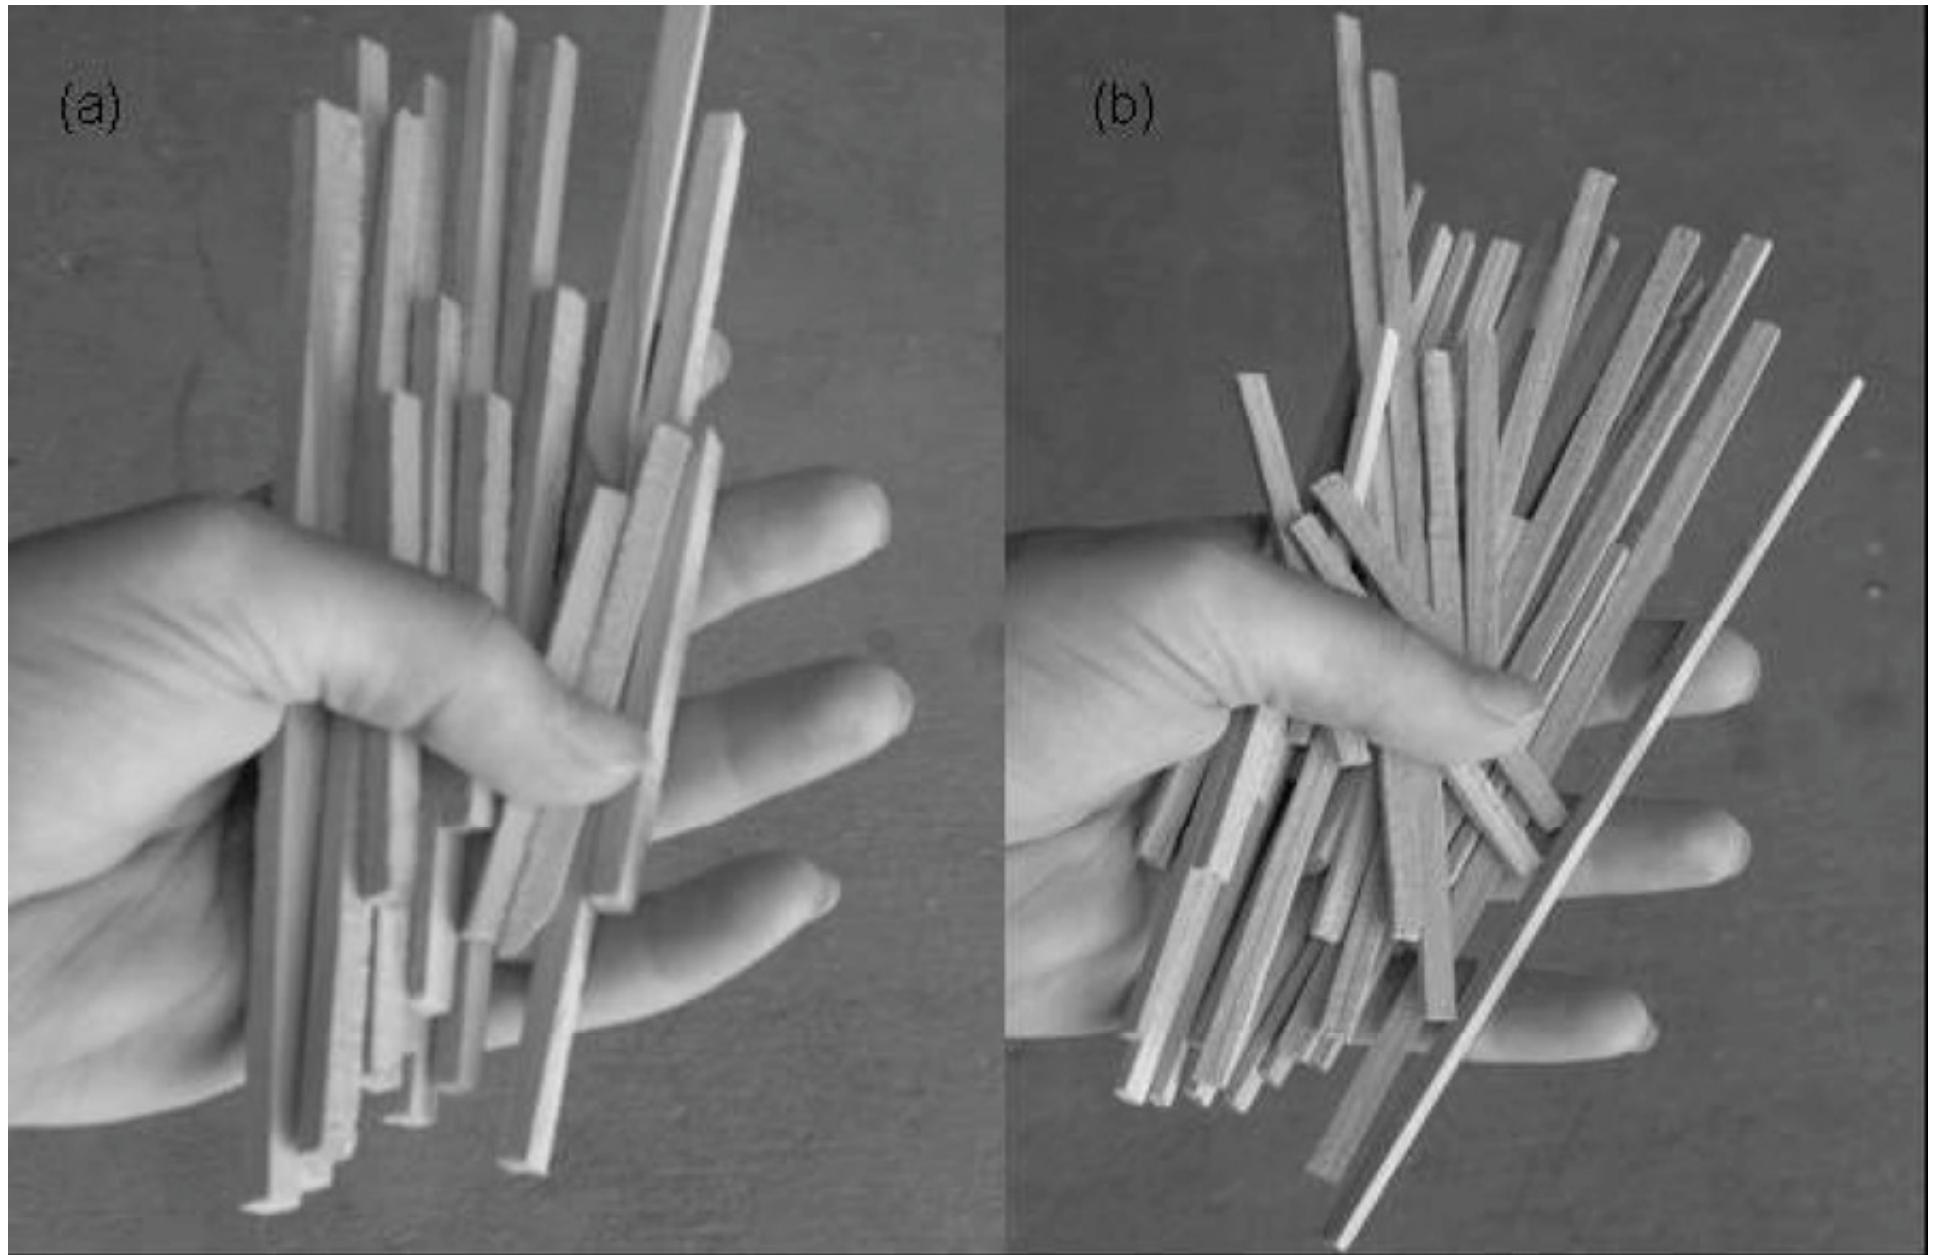

Sand Fences

Coastal dune area, USA.

Surface cover

- Wood chips, agricultural straw and other materials spread on surface
 - Widely used in the control of wind erosion from agricultural areas
- Agricultural straw is problematic in an area of high winds and sand flux rates, unless it is anchored or crimped to the surface
- Wood strand material
 - stable to wind speeds of 18 m/sec (40 mph),
 - wheat straw stable to only 6.5 m/s (14.5 mph).
 - PM10 emission reductions of 90% compared to bare soil were observed in these experiments (*Copeland et al., 2009*).
